PROPOSED SOLUTIONS

Below all curves and surfaces that appear are orientable and nice enough. Figures are from Thomas'.

1. (a) [2pts] What does an orientation mean on a surface $S \subset \mathbb{R}^3$?

(b) [2pts] What is the induced orientation on the boundary of an oriented surface?

(c) [8pts] State Stokes's Theorem in \mathbb{R}^3 . Explain every object that appears in the expression.

TRUE or FALSE... 6 points each... Either justify shortly or refute. Refuting is a proof; you can do this by giving a counterexample. Here $\Omega \subset \mathbb{R}^2$ open, $f : \Omega \rightarrow \mathbb{R}$, $\mathbf{F} : \Omega \rightarrow \mathbb{R}^2$; $D \subset \mathbb{R}^3$ open, $g : D \rightarrow \mathbb{R}$. The functions all are many times differentiable.

(d) If f is the div of some vector field \mathbf{F} then $\text{grad } f = \mathbf{0}$.

FALSE: $\vec{F} = (x^2, y^2)$, $f = \text{div } \vec{F} = 2x + 2y$, $\text{grad } f = (2, 2) \neq \mathbf{0}$.

(e) If S is a closed surface (i.e. S is topologically closed with $\partial S = \emptyset$) then the flux of any vector field through S is zero.

FALSE: $\vec{F}(x, y, z) = (x, y, z) / \|(x, y, z)\|$, $S = \text{unit sphere, oriented outwards}$

$$\iint_S \vec{F} \cdot \vec{n} \, dA = \iint_S dA = 4\pi \neq 0.$$

(f) If $\text{curl } \mathbf{G} = 0$ then for some function g , $\mathbf{G} = \text{grad } g$ on $D \subset \mathbb{R}^3$.

FALSE: Existence of g depends on the topology of D .

Let $\mathbf{G} = \left(\underbrace{\frac{-y}{x^2+y^2}}_P, \underbrace{\frac{x}{x^2+y^2}}_Q, 0 \right)$. (Here $\text{dom } \mathbf{G} = \mathbb{R}^3 - \{z\text{-axis}\}$)

↳ not "simply connected"

$$\text{curl } \mathbf{G} = (Q_x - P_y) \vec{k} = \frac{2}{x^2+y^2} + \frac{-2x^2}{(x^2+y^2)^2} + \frac{-2y^2}{(x^2+y^2)^2} = 0$$

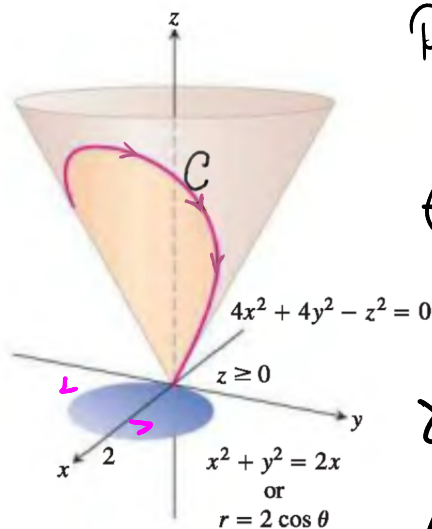

However, for $C = \{x^2+y^2=1, z=0\}$ oriented positively,

$$\int_C \vec{G} \cdot d\vec{x} = \int_0^{2\pi} \left(\frac{-\sin\theta}{1} (C\theta)' + \frac{C\theta}{1} (S\theta)' \right) d\theta = 2\pi \neq 0$$

$C: (C\theta, S\theta)$

Hence \vec{G} is not conservative. \vec{G} cannot be a gradient.

2. Find the work done by the vector field $\mathbf{H} = \mathbf{i} + z\mathbf{j} - z/4\mathbf{k}$ along the curve C on the cone in the figure, which projects down to the boundary of a planar 2-disk. The curve C is oriented as in the figure.

Parametrize C respecting the orientation:

$$2\sqrt{2x} = 2\sqrt{4C^2\theta}$$

$$\theta \in [-\pi/2, \pi/2], \quad \gamma(\theta) = (rC\theta, rS\theta, \sqrt{4x^2+4y^2})$$

$$= (2C^2\theta, \underbrace{2C\theta S\theta}_{S2\theta}, 4C\theta)$$

$$\gamma'(\theta) = (4C\theta(-S\theta), 2C2\theta, -4S\theta)$$

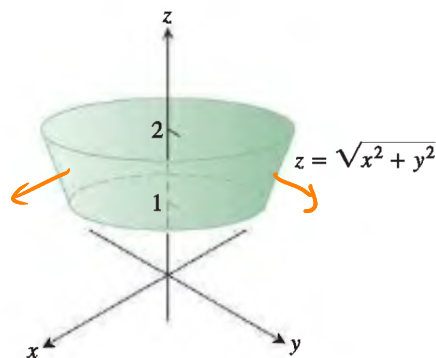

$$\int_C \vec{H} \cdot d\vec{x} = \int_{-\pi/2}^{\pi/2} (1, 4C\theta, -\frac{4C\theta}{4}) \cdot \gamma'(\theta) d\theta$$

$$= \int_{-\pi/2}^{\pi/2} (4C\theta S\theta + 8C\theta \cdot C2\theta + 4C\theta S\theta) d\theta$$

$$= 8 \cdot \int_{-\pi/2}^{\pi/2} C\theta (1 - 2S^2\theta) d\theta = 8 \left(2 - \frac{2}{3} S^3\theta \right) \Big|_{-\pi/2}^{\pi/2}$$

$$= 16/3$$

3. (a) Consider the **outwards** oriented surface K in the figure (a portion of a cone, called a *cone frustum*). K is a surface with boundary, which is the disjoint union of two circles.

Determine a one-to-one C^1 parametrization φ [6 pts] for (at least a portion of) K supplying the given orientation [6 pts], and with the condition that the domain of φ is open in \mathbb{R}^2 . What is the domain of your parametrization?

$$\varphi: \Omega = \{1 \leq u^2 + v^2 \leq 4\} \rightarrow \mathbb{R}^3$$

$$\varphi(u, v) = (-u, v, \sqrt{u^2 + v^2})$$

this provides the right orientation.

Note: $\varphi_u = (-1, 0, u/\sqrt{u^2 + v^2})$, $\varphi_v = (0, 1, v/\sqrt{u^2 + v^2})$

$\varphi_u \times \varphi_v = (-u/\sqrt{u^2 + v^2}, v/\sqrt{u^2 + v^2}, -1)$

- (b) Compute the area of K using a surface integral. (OK, everybody knows the result from high school. Here I want you to compute the area using math234 technology.)

$$\begin{aligned}
 \text{area}(K) &= \iint_K dA = \iint_{\Omega} \|\varphi_u \times \varphi_v\| dA_{u,v} \\
 &= \iint \left(1 + \frac{u^2}{u^2 + v^2} + \frac{v^2}{u^2 + v^2}\right)^{1/2} du dv = \sqrt{2} (4\pi - \pi) = 3\sqrt{2}\pi
 \end{aligned}$$

4. Consider the surface K in the previous question. We build a closed surface Σ by gluing a pair of horizontal 2-disks to K along their boundaries. Then we orient Σ **outwards**. Now compute the flux

$$\iint_{\Sigma} \mathbf{G} \cdot \mathbf{n} \, dA$$

for the vector field $\mathbf{G} = (x^2 + \tan(yz/4))\mathbf{i} + (e^{x^2z} - 2xy)\mathbf{j} + xz\mathbf{k}$.

Observe \mathbf{G} is defined in $W \stackrel{\text{def}}{=} \text{solid bounded by } \Sigma$.

Moreover Σ is oriented correctly. Then we can use

Divergence thm: $\iint_{\Sigma} \mathbf{G} \cdot \mathbf{n} = \iiint_W \text{div} \mathbf{G} \, dV$ orientation of Σ is right

$$\begin{aligned} \text{div } \mathbf{G} = 2x - 2x + x &\Rightarrow \iiint_W x \, dV = \int_1^2 \int_0^{2\pi} \int_0^x x \cdot r \, dr \, d\theta \, dz \\ &\quad \text{cylindrical} \\ &\quad \text{coords} \\ &= \int_1^2 \int_0^{2\pi} \int_0^x r^2 \cos \theta \, dr \, d\theta = 0 \end{aligned}$$
